Character info	0x24	Bashes Counter	value stays in place while gameplay goes from 3 > 2	16bit	0x8d4	0		<50?			

Starting pointer is held in memory at 0x50b944

Going forward in the list will have an addaddress chain that goes: Starting pointer > +10 > (+14) # of node times > +0 > +Final Offset

Going backward in the list will have an addaddress chain that goes: Starting pointer > +44 > +30 > (+10) # of node times > +0 > +Final Offset

The above going backward chain only works in some instances, other times it seems to access a whole other linked list? Very confusing, might need further research if other data that cannot be found is eventually needed (Looking at you Gamecube port)

Nodes listed from the start can be moved a node further in the list every time a new object spawns, and a node from the end can be moved closer to the end every time a node is destroyed

Character info nodes seem to be unique other than in the hub world where there is one per baby

Royal Ransom Set Design
Linked List Data

For instance, the logic to test if the snowcone counter in level 0x1b changes from 0x20 to 0x1f at the start of the level before nothing else spawns would look like

Mem

16-bit

Node Type 0x111328 Size 16-bit Final Offset 0x8d4 Nodes from start 4 8-bit = Value 0x1b Mem Level AddAddress Mem 32-bit 0x50b944 AddAddress Mem 32-bit 0x10 AddAddress Mem 32-bit 0x14 AddAddress Mem 32-bit 0x14 Mem 32-bit 0x14 AddAddress Mem 32-bit 0x14 Remember AddAddress Recall 0x0 AddAddress Mem 32-bit 32-bit AddAddress Mem 0xd8 AndNext Mem 32-bit 0xec = Value 0x111328 Recall AddAddress AddAddress Mem 32-bit 0x0 16-bit 0x8d4 = Value 0x20 AndNext Delta AddAddress Recall AddAddress 32-bit 0x0 Mem

Level Check
Access the Pointer
Access the Node
Testing Node Type
Delta Check
Mem Check

We want to go from the start of the list,

Four 0x14's, since we want the 4th node

so starting with the main pointer then

0x10, instead of 0x44 and 0x30

Access the Pointer More specifically, access the pointer to the node

0x8d4

AddAddressing the 0x0 after the remember is so we can check multiple nodes in a row See to the right for an example

= Value

0x1f

For checking several nodes in a row for the snowcone data, the logic may look like this, with the purple chunk from the example on the left collapsed into a single line

			Mem	8-bit	Level	=	Value	0x1b	
		AddAddress	Mem	32-bit	0x50b944				
		Remember	Mem	32-bit	0x10				
	0th node		Purple	chunk co	pied from left	with a	ddHits in the last	line	
		AddAddress	Recall						
		Remember	Mem	32-bit	0x14				
	1st node		Purple	chunk co	pied from left	with a	ddHits in the last	line	
		AddAddress	Recall						
		Remember	Mem	32-bit	0x14				
	2nd node		Purple	chunk co	pied from left	with a	ddHits in the last	line	
		AddAddress	Recall						
		Remember	Mem	32-bit	0x14				
	3rd node		Purple	chunk co	pied from left	with a	ddHits in the last	line	
		AddAddress	Recall						
		Remember	Mem	32-bit	0x14				
	4th node	Purple chunk copied from left with addHits in the last line							
		AddAddress	Recall						
		Remember	Mem	32-bit	0x14				
	5th node		Purple	chunk co	pied from left	with a	ddHits in the last	line	
			Value		0x0	=	Value	0x1	(1)

The addhits are neccessary to act as an orNext chain without needing to split this logic into seperate alt groups, as the Remember / Recall is impoartant to keep logic length down to fit in the 64k character limit

This logic in the code is done with the function

comparison(data.levelIDLoaded, '=', 0x1b)
data.chainLinkedListRange(0, 5, ARRAY, true)
"0=1.1."

The inputs of the middle line being

- 0 Start at node 0
- 5 End at node 5

ARRAY - an array with an element per check you want to do per node, in this case 3.

The three bit of logic to the left that are green, orange, and red

2

true - We want to go forward through the list, not backwards
